

PHASE 3 — PROJECT DESIGN

Script-Controlled ACL – Restrict Record Access Based on Field Value

Project Phase: Project Design | Platform: ServiceNow | Project Area: Access Control

Architecture Design

The project design separates data, security configuration and access decisions. The protected data is stored in u_institution_details; ACL records define the operation and role requirements.

High-Level Design

The READ ACL is configured as a record ACL for u_institution_details, with Advanced enabled, bb1 as the required role and the documented EEE condition.

ACL Design

ACL	Type	Operation	Role
READ	record	read	bb1
CREATE	record	create	bb2
WRITE	record	write	bb3
DELETE	record	delete	bb4

The source specifies that CREATE, WRITE and DELETE do not need a data condition. The READ ACL uses the documented EEE branch condition.

Four-Operation ACL Design

Script Decision Design

The supplied READ script follows three logical decisions: allow administrators, allow users with bb1, and deny all others.

Step	Decision
1	If gs.hasRole('admin') → return true
2	If gs.hasRole('bb1') → return true
3	Otherwise → return false

The ACL configuration and script therefore work together to enforce the documented access behavior.
